2.2.1 INTRODUCTION.

The primary guidance navigation and control (PGNCS) system measures spacecraft attitude and velocity, determines trajectory, controls spacecraft attitude, controls the thrust vector of the service propulsion engine, and provides short information and display data. Primary determination of the spacecraft velocity and position and computation of the trajectory parameters is accomplished by the manned space flight network (MSFN).

The PGNCS system consists of three subsystems as follows:

- Inertial subsystem (ISS)
- Computer subsystem (CSS)
- Optics subsystem (OSS).

The inertial subsystem is composed of an inertial measurement unit (IMU), part of the power and servo assembly (PSA), part of the controls and displays, and three inertial coupling data units (CDUs). The IMU provides an inertial reference with a gimbaled, three-degree-of-freedom, gyro-stabilized stable platform.

The computer subsystem is composed of the command module computer (CMC) and two display and keyboard panels (DSKYs), which are part of the controls and displays. The CMC is a digital computer which processes and controls information to and from the IMU, the optics, DSKYs, and stores programs and reference data.

The optics subsystem is composed of a scanning telescope (SCT), a sextant (SXT), drive motors for positioning the SCT and SXT, parts of the PSA, part of the controls and displays, and two optics CDUs. The SCT and SXT are used to determine the spacecraft position and attitude with relation to stars and/or landmarks.

The three G&N subsystems are configured to enable the CSS and OSS to be operated independently. This allows continued use of the CSS and/or OSS in the event of a malfunction in one of these subsystems or in the ISS. System power requirements and reference signals are provided by the power and servo assembly (PSA). Major components
of the system are located in the command module lower equipment bay (figure 2.2-1). System circuit breakers, caution and warning indicators, and one of the DSKYs are located on the main display console.

2.2.2

FUNCTIONAL DESCRIPTION.

The primary guidance navigation and control system provides capabilities for the following:

- Inertial velocity and position (state vector) computation
- Optical and inertial navigation measurements
- Spacecraft attitude measurement and control
- Generation of guidance commands during CSM-powered flight and CM atmospheric entry.

The PGNCS system is initially activated and aligned during the prelaunch phase. During the ascent phase, the system measures velocity and attitude, computes position, compares the actual spacecraft trajectory with a predetermined trajectory, and displays pertinent data. The flight crew uses the displayed information as an aid for decision to abort or continue the mission.

During periods when on-board velocity and/or attitude change sensing is not required, the IMU can be placed in standby operation to conserve electrical power. The CMC is used more extensively than the IMU; however, it can also be placed in standby operation to conserve electrical power. When the guidance and navigation function is to be restored, the IMU and CMC are reactivated, with the CMC using the last computed velocity as the basis for further velocity computations. New positional data must be acquired from optical sightings or MSFN through telemetry or voice communications.

Initial position and attitude information as well as periodic updating of this information is made through use of the optics. This is accomplished by the navigator making two or more landmarks, star-landmark, star-horizon, and/or star sightings. The sightings are made by acquiring the star-landmark or star-horizon with the SCT and/or SXT. When the viewed object is centered, a mark command is initiated. The CMC reads the optics angles, IMU angles, and time, in conjunction with internal programs to determine the spacecraft position. This position information and the spacecraft velocity are used to compute an estimated trajectory. The actual trajectory is compared with previous trajectory data to generate the trajectory error, if any, for further reference. Optical measurements are also used in aligning the IMU to a specific reference orientation.
The IMU (figure 2.2-3) contains three inertial rate integrating gyros (IRIGs) and three pulsed-integrating pendulous accelerometers (PIPAs). The IRIGs and PIPAs are mounted on the stable platform which is gimbaled to provide three degrees of freedom. The stable platform inertial reference is maintained by the IRIGs in conjunction with electronic stabilization loops. Any displacement of the platform is sensed by the IRIGs, which produce output signals representative of the magnitude and direction of displacement. The IRIG signals are applied to servo amplifiers, which condition the signals to drive gimbal torque motors. The gimbal torque motors then restore the initial platform orientation by driving the gimbals until the IRIG signals are nulled.

The PIPAs are orthogonally mounted and sense changes in spacecraft velocity. An acceleration or deceleration results in output signals which are representative of the magnitude and direction of the velocity change. The output signals are applied to the CMC which uses the information to update spacecraft velocity data. Continual updating of velocity information, with respect to the initial spacecraft position and trajectory, enables the CMC to provide current velocity, position, and trajectory information.

The IMU also provides a space-stabilized reference for spacecraft attitude sensing and control. Attitude change sensing is accomplished by monitoring the spacecraft attitude with reference to the stable platform. Resolvers are mounted at the gimbal axes to provide signals representative of the gimbal angles. Inertial CDUs repeat the platform attitude. Attitude monitoring is afforded by comparing the inertial CDU angles with the CMC desired angles. If the angles differ, error signals are generated. If the attitude error is larger than the selected deadband limits, the CMC fires the appropriate RCS engines. The spacecraft is rotated back to the initial reference attitude and the error signals are nulled (within deadband limits).

The CMC provides automatic execution of computer programs, automatic control of ISS and OSS modes, and in conjunction with the DSKYs, manual control of ISS and OSS modes and computer displays. The CMC contains a two-part memory which consists of a large non-erasable section and a smaller erasable section. Nonerasable memory contains mission and system programs, and other predetermined data which are wired in during assembly. Data readout from this section is nondestructive and cannot be changed during operation. The erasable section of memory provides for data storage, retrieval, and operations upon measured data and telemetered information. Data readout from this section is destructive, permitting changes in stored data to be made as desired. Information within the memory may be called up
for display on the two DSKYs. The DSKYs enable the flight crew to enter data or instructions into the CMC, request display of data from CMC memory, and offer an interrupt control of CMC operation. The CMC timing section provides timing signals of various frequencies for internal use and to other on-board systems which require accurate or synchronized timing. Data within the CMC is transmitted to MSFN through a "downlink" telemetry function. Telemetered data is transmitted as a function of a CMC program or by request from MSFN. Data within the CMC may be updated through "uplink" telemetry from the MSFN. The CMC performs guidance functions by executing internal programs using predetermined trajectory parameters, attitude angles from the inertial CDUs, velocity changes from the PIPAs, and commands from the DSKYs (crew) to generate control commands. The navigation function is performed by using stored star-landmark or star-horizon data, optics angles from the optics CDUs, and velocity changes from the PIPAs in the execution of navigation programs.

The optics provide accurate star and landmark angular measurements. Sightings are accomplished by the navigator using the SXT and SCT. The optics are positioned by drive motors commanded by the optics hand controller or by the CMC. The shaft axes are parallel. Trunnion axes may be operated in parallel or offset, as desired. The SCT is a unity power instrument providing an approximate 60-degree field of view. It is used to make landmark sightings and to acquire and center stars or landmarks prior to SXT use. The SXT provides 28-power magnification with a 1.8-degree field of view. The SXT has two lines of sight, enabling it to measure the included angle between two objects. This requires two lines of sight which enable the two viewed objects to be superimposed. For a star-landmark or star-horizon sighting, the landmark line of sight is centered along the SXT shaft axis. The star image is moved toward the landmark or horizon by rotating the shaft and trunnion axes until the two viewed objects are superimposed. The shaft and trunnion angles are repeated by the optic CDUs. When the navigator is satisfied with image positions, he issues a marked command to the CMC. The CMC reads the optics CDU angles, IMU CDU angles, and time and computes the position of the spacecraft. The CMC bases the computation on stored star and navigator-supplied landmark data which may also be used by the CMC to request specific stars for navigational sightings. Two or more sightings, on two or more different stars, must be taken to perform a complete position determination.
2.2.3 MAJOR COMPONENT/SUBSYSTEM DESCRIPTION.

2.2.3.1 Inertial Subsystem.

The function of the inertial subsystem is to provide a space-stabilized inertial reference from which velocity changes and attitude changes can be sensed. It is composed of the navigation base (NB), the inertial measurement unit (IMU), parts of the power and servo assembly (PSA), parts of the control and display panels, and three coupling data units (CDUs).

2.2.3.1.1 Navigation Base.

The navigation base (NB) is the rigid, supporting structure which mounts the IMU and optical instruments. The NB is manufactured and installed to close tolerances to provide accurate alignment of the equipment mounted on it. It also provides shock-mounting for the IMU and optics.

2.2.3.1.2 Inertial Measurement Unit.

The inertial measurement unit (IMU) is the main unit of the inertial subsystem. It is a three-degree-of-freedom stabilized platform assembly, containing three inertial rate integrating gyros (IRIGs), and three pulsed-integrating pendulous accelerometers (PIPAs). The stable member itself is machined from a solid block of beryllium with holes bored for mounting the PIPAs and IRIGs.

The stable platform attitude is maintained by the IRIGs, stabilization loop electronics, and gimbal torque motors. Any displacement of the stable platform or gimbal angles is sensed by the IRIGs which generate error signals. IRIG error signals are resolved, amplified, and applied to stabilization loop electronics. The resultant signal is conditioned and applied to the gimbal torque motors, which restore the desired attitude.

The stable platform provides a space-referenced mount for three PIPAs, which sense velocity changes. The PIPAs are mounted orthogonally to sense the velocity changes along all three axes. Any translational force experienced by the spacecraft causes an acceleration or deceleration which is sensed by one or more PIPAs. Each PIPA generates an output signal proportional to the magnitude and direction of velocity change. This signal, in the form of a pulse train, is applied to the CMC. The CMC will use the signal to update the velocity information, and will also generate signals to enable the torquing of each PIPA ducosyn back to null.
The temperature control system is a thermostatic system that
maintains the IRIG and PIPA temperatures within their required limits
during both IMU standby and operate modes. Heat is applied by end-
mount heaters on the inertial components, stable member heaters, and
a temperature control anticipatory heater. Heat is removed by con-
vection, conduction, and radiation. The natural convection used during
IMU standby modes is changed to blower-controlled, forced convection
during IMU operating modes. IMU internal pressure is normally
between 3.5 and 15 psia enabling the required forced convection. To
aid in removing heat, a water-glycol solution passes through coolant
passages in the IMU support gimbal. Therefore, heat flow is from the
stable member to the case and coolant. The temperature control sys-
tem consists of the temperature control circuit, the blower control
circuit, and the temperature alarm circuit. A separate external
temperature control system is also provided for test configurations but
will not be discussed in this manual.

2.2.3.1.3 Coupling Data Unit.

The CDU, an all electronic device, is used as an interface
element between the ISS and CSS, the OSS and CSS, and the CSS and
various controls and displays. It functions primarily as an analog-to-
digital (A/D) or digital-to-analog (D/A) converter. There are five,
almost identical, loops, one each for the inner, middle, and outer
IMU gimbals, and one each for the shaft and trunnion optical axes.
The ISS portion of the CDU performs the following functions:

a. Converts IMU gimbal angles from analog-to-digital form, and
supplies the CMC with this information.

b. Converts digital signals from the CMC to either 800-cps or
direct-current signals.

c. Controls the moding of the ISS through logical manipulation of
computer discretes.

The analog signal from the 1X and 16X resolvers, located on the
IMU gimbals, is transmitted to the CDU. This angular information,
proportional to the sine and cosine of the gimbal angle, is converted to
digital form with one pulse to the CMC equivalent to 40 arc-seconds of
gimbal movement.

During coarse align, attitude error display, and Saturn takeover
modes, the ISS channels of the CDU provide the digital to analog con-
version of the CMC output to generate an a-c or d-c output. The a-c
output is applied to the servo amplifiers of the PSA to drive the gimbals
to the desired angle, and is also applied to the FDAI for deflection of
the attitude error needles. The d-c signal is applied to the Saturn
Flight Control Computer which will gimbal the Saturn engine or pro-
vide commands to the Saturn attitude control system.
2.2.3.1.4 Power and Servo Assembly.

The purpose of the power and servo assembly (PSA) is to provide a central mounting point for the majority of the G&N system power supplies, amplifiers, and other modular electronic components.

The PSA is located on the lower D&C panel rack directly below the IMU. It consists of 42 modules mounted to a header assembly. Connectors and harnessing are integral to the construction of the header assembly, and G&N harness branches are brought out from the PSA header. A thin cover plate is mounted on the PSA, providing a hermetic seal for the interior. During flight, this permits pressurization of the PSA to remain at 15 psi. Connectors are available at the PSA for measuring signals at various system test points.

2.2.3.2 Computer Subsystem.

The computer subsystem (CSS) consists of the command module computer (CMC), and two display and keyboard panels (DSKYs). The CMC and one DSKY are located in the lower equipment bay. The other DSKY is located on the main display console.

2.2.3.2.1 Command Module Computer.

The CMC is a core memory, digital computer with two types of memory, fixed and erasable. The fixed memory permanently stores navigation tables, trajectory parameters, programs, and constants. The erasable memory stores intermediate information.

The CMC processes data and issues discrete control signals, both for the PGNCS and the other spacecraft systems. It is a control computer with many of the features of a general purpose computer. As a control computer, the CMC aligns the stable platform of the inertial measurement unit (IMU) in the inertial subsystem, positions the optical unit in the optical subsystem, and issues control commands to the spacecraft. As a general purpose computer, the CMC solves guidance problems required for the spacecraft mission. In addition, the CMC monitors the operation of the PGNCS and other spacecraft systems.

The CMC stores data pertinent to the flight profile that the spacecraft must assume in order to complete its mission. This data, consisting of position, velocity, and trajectory information, is used by the CMC to solve the various flight equations. The results of various equations can be used to determine the required magnitude and direction of thrust required. Corrections to be made are established by the CMC. The spacecraft engines are turned on at the correct time, and steering
signals are controlled by the CMC to reorient the spacecraft to a new trajectory, if required. The inertial subsystem senses acceleration and supplies velocity changes to the CMC for calculating the total velocity. Drive signals are supplied from the CMC to coupling data unit (CDU) and stabilization gyros in the inertial subsystem to align the gimbal angles in the IMU. Error signals are also supplied to the CDU to provide steering capabilities for the spacecraft. CDU position signals are fed to the CMC to indicate changes in gimbal angles, which are used by the CMC to keep cognizant of the gimbal positions. The CMC receives mode indications and angular information from the optical subsystem during optical sighting. This information is used by the CMC to calculate present position and orientation, and is used to refine trajectory information. Optical subsystem components can also be positioned by drive signals supplied from the CMC.

CMC Organization. The CMC is functionally divided into seven blocks: (See figure 2.2-3),

1. Timer
2. Sequence generator
3. Central processor
4. Memory
5. Priority control
6. Input-output
7. Power.

Timer. The timer generates all the necessary synchronization pulses to ensure a logical data flow from one area to another within the CMC. It also generates timing waveforms which are used by (1) the CMC’s alarm circuitry, and (2) other areas of the spacecraft for control and synchronization purposes.

The master clock frequency is generated by an oscillator and is applied to the clock divider logic. The divider logic divides the master clock input into gating and timing pulses at the basic clock rate of the computer. Several outputs are available from the pulses at the basic clock rate of the computer. Several outputs are available from the scaler, which further divides the divider logic output into output pulses and signals used for gating, to generate rate signal outputs and for the accumulation of time. Outputs from the divider logic also drive the time pulse generator which produces a recurring set of time pulses. This set of time pulses defines a specific interval (memory cycle time) in which access to memory and word flow take place within the computer.

The start-stop logic senses the status of the power supplies and specific alarm conditions in the computer, and generates a stop signal which is applied to the time pulse generator to inhibit word flow. Simultaneously, a fresh-start signal is generated which is applied to
all functional areas in the computer. The start-stop logic, and subsequently word flow in the computer, can also be controlled by inputs from the computer test set (CTS) during pre-installation systems and subsystem tests.

Sequence Generator. The sequence generator directs the execution of machine instructions. It does this by generating control pulses which logically sequence data throughout the CMC. The control pulses are formed by combining the order code of an instruction word with synchronization pulses from the timer.

The sequence generator contains the order code processor, command generator, and control pulse generator. The sequence generator executes the instructions stored in memory by producing control pulses which regulate the data flow of the computer. The manner in which the data flow is regulated among the various functional areas of the computer and between the elements of the central processor causes the data to be processed according to the specifications of each machine instruction.

The order code processor receives signals from the central processor, priority control, and peripheral equipment (test equipment). The order code signals are stored in the order code processor and converted to coded signals for the command generator. The command generator decodes these signals and produces instruction commands. The instruction commands are sent to the control pulse generator to produce a particular sequence of control pulses, depending on the instruction being executed. At the completion of each instruction, new order code signals are sent to the order code processor to continue the execution of the program.

Central Processor. The central processor performs all arithmetic operations required of the CMC, buffers all information coming from and going to memory, checks for correct parity on all words coming from memory, and generates a parity bit for all words written into memory.

The central processor consists of the flip-flop registers, the write, clear, and read control logic, write amplifiers, memory buffer register, memory address register and decoder, and the parity logic. All data and arithmetic manipulations within the CMC take place in the central processor.

Primarily, the central processor performs operations indicated by the basic instructions of the program stored in memory. Communication within the central processor is accomplished through the write amplifiers. Data flows from memory to the flip-flop registers or vice
versa, between individual flip-flop registers, or into the central processor from external sources. In all instances, data is placed on the write lines and routed to specific register, or to another functional area under control of the write, clear, and read logic. This logic section accepts control pulses from the sequence generator and generates signals to read the content of a register onto the write lines, and write this content into another register of the central processor or to another functional area of the CMC. The particular memory location is specified by the content of the memory address register. The address is fed from the write lines into this register, the output of which is decoded by the address decoder logic. Data is subsequently transferred from memory to the memory buffer register. The decoded address outputs are also used as gating functions within the CMC.

The memory buffer register buffers all information read out or written into memory. During read out, parity is checked by the parity logic and an alarm is generated in case of incorrect parity. During write-in, the parity logic generates a parity bit for information being written into memory. The flip-flop registers are used to accomplish the data manipulations and arithmetic operations. Each register is 16 bits or one computer word in length. Data flows into and out of each register as dictated by control pulses associated with each register. The control pulses are generated by the write, clear, and read control logic.

External inputs through the write amplifiers include the content of both the erasable and fixed memory bank registers, all interrupt addresses from priority control, control pulses which are associated with specific arithmetic operations, and the start address for an initial start condition. Information from the input and output channels is placed on the write lines and routed to specific destinations either within or external to the central processor. The CTS inputs allow a word to be placed on the write lines during system and subsystem tests.

Registers. Registers A, L, Q, Z, and B consist of 16 bit positions each. These are numbered 16 through 1 reading from left to right. Register E BANK consists of three bit positions numbered 11 through 9. Register S consists of 12 bit positions numbered 12 through 1. Register SQ consists of seven bit positions, SQ, EXT, 16 and 14 through 10. Registers X and Y comprise the adder and each register consists of 16 bit positions. The 16 output gates of the adder are called register U; note, however, that U is not a register in the sense of the flip-flop registers comprising the central processor. Register U and the write amplifiers each consists of 16 bit positions numbered 16 through 1. All registers mentioned so far may contain addresses, a code, etc. They do not, however, contain a parity bit. Whenever a number is contained in these registers, the lowest order bit is stored
in bit position 1 and the highest order bit is stored in bit position 14.
The sign bit is stored in bit position 16. A zero in this bit position
signifies a positive number and a one signifies a negative number. Bit
position 15 is used for storing either the overflow or underflow bit.

Register G serves as a buffer between the central processor and
memory. It consists of 16 bit positions numbered 16 through 1. Any
parity bit received from memory is transferred to the parity block but
not to the central processor register. The 16 inputs to the parity block
are numbered 16 and 14 through 0. No provision is made for entering
an overflow bit into the parity block.

Register A is called the "accumulator." It contains the results
of arithmetic operations.

Register L is called the "lower order accumulator." It contains
the least significant bits of the product or quotient after a multiplication
or division process.

Register B is called the "buffer register." It also provides a
means of complementing since its reset side can also be interrogated.
The reset side is sometimes called "register C."

The Z register is the program counter. It contains the address
of the next instruction word in the program. As each instruction is
executed, this register is incremented by one because the instruction
words usually are stored sequentially in memory.

The Q register is named the "return address register." When
the CMC transfers control to another program or routine, the contents
of the Z register are stored in register Q. When the CMC returns to
the original program, register Q contains the address of the appropriate
instruction.

The write amplifiers provide the current driving capabilities for
the registers. These amplifiers in no way store information; they
simply route information.

Register S contains the address of the word to be called out from
memory. Register E BANK is also used when erasable memory is
addressed. Register F BANK is used when fixed memory is addressed.

Memory. Memory provides the storage for the CMC and is
divided into two sections: erasable memory and fixed memory.
Erasable memory can be written into or read from; its readout is
destructive. Fixed memory cannot be written into and its readout is
nondestructive.
The CMC has erasable and fixed memories. The erasable memory can be written into and read out of; fixed memory can only be read out of. Erasable memory stores intermediate results of computations, auxiliary program information, and variable data supplied by external inputs from the FCNCS and other systems of the spacecraft. Fixed memory stores programs, constants, and tables. There is a total of 38,912, sixteen bit word storage locations in fixed and erasable memories. It should be noted that the majority of the memory capacity is in fixed memory (36,864 word locations). Both memories are magnetic core storage devices; however, the cores are used differently in each type of memory. It is assumed that the reader is familiar with the basic magnetic properties of a ferrite core as described by a square hysteresis curve. A core is a static storage device having two stable states. It can be magnetized in one or two directions by passing a sufficient current, I, through a wire which pierces the core. The direction of current determines the direction of magnetization. The core will retain its magnetization indefinitely until an opposing current switches the core in the opposite direction. Wires carrying current through the same core are algebraically additive. Sense wires which pierce a switched core will carry an induced pulse.

Priority Control. Priority control establishes a processing priority of operations which must be performed by the CMC. These operations are a result of conditions which occur both internally and externally to the CMC. Priority control consists of counter priority control and interrupt priority control. Counter priority control initiates actions which update counters in erasable memory. Interrupt priority control transfers control of the CMC to one of several interrupt subroutines stored in fixed memory.

The start instruction control restarts the computer following a hardware or program failure. The counter instruction control updates the various counters in erasable memory upon reception of certain incremental pulses. The counter instruction control is also used during test functions to implement the display and load requests provided by the computer test set. The interrupt instruction control forces the execution of the interrupt instruction (RUPTOR) to interrupt the current operation of the computer in favor of a programmed operation of a higher priority.

Input-Output. The input-output section routes and conditions signals between the CMC and other areas of the spacecraft. In addition to the counter interrupt and the program interrupts previously described, the CMC has a number of other inputs derived from its interfacing hardware. These inputs are a result of the functioning of the hardware,
or an action by the operator of the spacecraft. The counter interrupts, in most cases, enable the CMC to process inputs representative of data parameters such as changes in velocity. The program interrupt inputs to the CMC are used to initiate processing of functions which must be processed a relatively short time after a particular function is present. The other inputs to the CMC, in general, enable the CMC to be cognizant of "conditions" which exist in its environment. These inputs are routed to CMC and are available to the CMCs programs through the input channels.

The outputs of the CMC fall in one of the following categories: data, control, or condition indications. Some of these outputs are controllable through the CMC program while others are present as a function of the CMC circuitry. All of the outputs which are controlled by the CMC programs are developed through the CMC output channels.

Channel 01 is the L register.
Channel 02 is the Q register.
Channel 03 the high-order scaler channel.
Channel 04 the low-order scaler channel.

Output Channel 05 has eight bit positions and is associated with the reaction control system jets.

Output Channel 06 has eight bit positions and is also associated with the reaction control system jets. A logic one in any of the bit positions will cause the appropriate reaction control jets to be fired. The outputs of this channel control the jets used for Z and Y translations, and the roll rotation. The logic is the same as for output channel 05. Assume that it was desired to perform a pure roll maneuver. One of the ways this could be implemented would be to have logic ones in bit positions 1 and 3 while all other bit positions contained a logic zero. There are other methods, of course, but these will not be detailed.

Channel 07 is the F EXT register. It is associated with the selection of word locations in fixed memory. This channel has three bit positions.

Output Channel 10 routes information contained in this channel to the DSKYs. The different configurations light various displays on the DSKYs.

Output Channel 11 routes information contained in bits 1 through 7 of this channel to the DSKYs. Bit 13 is routed to the SCS system.
Output Channel 12 consists of 15 bit positions, 14 of which are presently used. The outbits are d-c signals sent to the spacecraft and PGNCS.

Output Channel 13 associates the first four bits of this channel with the VHF ranging. Bit positions 12 through 14 have been covered under program interrupt priority control.

Output Channel 14 associates bit positions 11 through 15 with the CDU drive control. This control generates the following pulse trains which are sent to the CDUs: CDUXDP (X CDU positive drive pulse), CDUXDM (X CDU negative drive pulse), CDUYDP, CDUYDM, CDUZDP, CDUZDM, TRNPD, TRNMD, SHAFTDP (shaft CDU positive drive pulse), and SHAFTDM. The CDU drive control also enters the following d-c signals into the counter-priority control to request the execution of a DINC instruction: X IMU, CDU, Y IMU, CDU, Z IMU CDU, S OP CDU and T OP CDU.

Signal X IMU CDU is generated when bit position 15 contains a logic one. Signal Y IMU CDU is generated when bit position 14 contains a logic one, signal Z IMU CDU when bit position 13 contains a logic one, signal T OP CDU when bit position 12 contains a logic one, and signal S OP CDU when bit position 11 contains a logic one. More than one of these signals can be generated simultaneously.

Once a desired quantity, e.g., -432, has been entered into a CDU counter, e.g., erasable memory address 0050, and output channel 14 has been properly set (logic 1 in bit position 15), the CDU drive control generates signal X IMU CDU which sets a flip-flop in counter priority control and commands the sequence generator to execute a DINC instruction. As the instruction is executed, the counter control is diminished by one to -431. The CDU drive control then generates a CDUXDM pulse and routes it to the X CDU. Since the priority flip-flop is still set, another DINC instruction is requested. This is repeated until the counter content has diminished to zero. Once the counter contains zero and a DINC instruction is executed, a signal is generated which clears bit position 15 of output channel 14, resets the priority cell, and stops the transmission of pulses.

The gyro drive control selects a gyro to be torqued positively or negatively, and then applies a 3200-cps pulse train to the appropriate gyro to accomplish this function. There are six signals associated with selection of the gyro and the direction in which it will be torqued: GYXP (drive gyro x positive), GYXM (drive gyro x negative), GYYP, GYYM, GYZP, and GYZM. The appropriate signal is determined by
the bit configuration of bits 7 through 9 of output channel 14. If bit positions 6 and 10 are a logic one, a 3200-cps pulse train is routed to the gyro electronics specified by bit positions 7 through 9, and a d-c signal is entered into the counter priority control which commands the sequence generator to perform a DINC instruction.

Assume that it is desired to torque the X-gyro in the negative direction by 123 pulses. The GYROS counter in counter priority control would be set to 123. Bit positions 7 through 9 would be 101 respectively, and bit positions 6 and 10 would be logic one. Each time a pulse is sent to the gyro, the GYROS counter is DINCed. The d-c signal to counter priority will remain until the GYROS counter goes to zero which will terminate the torquing.

Input Channel 15. This channel consists of five bit positions. When a key on the main panel DSKY is pressed, a unique five-bit code is entered into this channel. The RUPT 5 interrupt routine is also developed whenever a key on the main panel DSKY is pressed.

Input Channel 16. This channel consists of seven bit positions. If the MARK pushbutton has been pressed, a logic one is entered into bit position 6. This would cause a KEYRUPT 2 (RUPT 6) interrupt routine.

If the MARK REJECT pushbutton has been pressed, a logic one is entered into bit position 7 of this channel. This will also cause a KEYRUPT 2 interrupt routine to be performed. When a key on the navigation panel DSKY is pressed, a unique five-bit code is entered into bit positions 1 through 5. The insertion of this code into input channel 16 initiates a KEYRUPT 2 interrupt routine.

Input Channels 17 through 27 are spares.

Input Channel 30 consists of 15 bit positions. The inputs to these positions are inverted and utilized as follows:

a. Bit Position 1 (ULLAGE THRUST PRESENT). This input is generated by the S-IVB instrumentation unit. If this input is a logic zero, it signifies that the action has occurred or has been commanded to occur.

b. Bit Position 2 (SM SEPARATE). This input originates in the mission sequencer and is a logic 0 when the service module is separated from the command module.

c. Bit Position 3 (SPS READY). A logic zero in this bit position indicates that the pilot has completed the SPS engine start checklist.

d. Bit Position 4 and 5 (S-IVB SEPARATE - ABORT, LIFT OFF). These inputs are generated in the S-IVB instrumentation unit. They indicate that the appropriate actions have occurred or have been commanded to occur.
e. Bit Position 7 (OCDU FAIL). This input is generated in the OSS and is a logic zero when a failure has occurred in one of the optical CDUs.

f. Bit Position 9 (IMU OPERATE). A binary zero in this bit position indicates that the IMU is turned on and is operating with no malfunctions.

g. Bit Position 10 (SC CONTROL OF SATURN). A logic zero in this bit position indicates that the SC has control over the SATURN stage.

h. Bit Position 11 (IMU GAGE). A logic zero in this bit position indicates that the IMU gimbals are at their null position.

i. Bit Position 12 (IMU CDU FAIL). A logic zero in this bit position indicates that a failure has occurred in one of the inertial CDUs.

j. Bit Position 13 (IMU FAIL). A logic zero in this bit position indicates that a malfunction has occurred in the IMU stab loops.

k. Bit Position 14 (ISS TURN ON REQUEST). A logic zero is inserted into this bit position when the ISS has been turned on, or commanded to be turned on.

l. Bit Position 15 (TEMP IN LIMITS). A logic one is inserted into this bit position if the stable member temperature has not exceeded its design limits. If the limit has been exceeded, a logic zero will be stored.

Input Channel 31, channel consists of 15 bit positions. Bit positions 1 through 6 receive their inputs from the rotational hand controller. A logic zero in any one of these bit positions is associated with roll, pitch, or yaw commands. Bit positions 7 through 12 receive their inputs from the translational hand controller. A logic zero in any one of these bit positions is associated with the X, Y, or Z translation commands.

A logic zero in bit position 13 indicates that the present SC attitude is being held and the hand controller is not being used. A logic zero in bit position 14 indicates that the SC is drifting freely, and that the GNC is not receiving inputs from the hand controller or minimum impulse controller. A logic zero in bit position 15 indicates that the GNC is controlling the present SC attitude and the hand controller is not commanding an attitude change. All inputs to this channel are inverted.

Input Channel 32, the first six bit positions of this channel receive their inputs from the minimum impulse controller. A logic zero in any of these bit positions is associated with the pitch, yaw, or roll motion commanded by the minimum impulse controller. Bit position 11 contains a logic zero while the LM is attached to the GCM. All inputs to this channel are inverted.
Input Channel 33, inputs to this channel are generated in the CMC and optics. A logic zero in bit position 2 indicates that the VHF Digital Ranging information is good. Bit positions 4 and 5 receive d-c signals from the optics control panel. The d-c signals are generated by switch and relay closures. A logic zero appears in bit position 10 if the BLOCK UPLINK switch is thrown to the BLOCK position. Bit positions 11 or 12 contain a logic zero if the uplink or downlink telemetry rates are too high. Bit position 13 contains a logic zero if a failure occurs in the accelerometer loops. All inputs to this channel are inverted.

Output Channels 34 and 35 provide 16 bit words including a parity bit for downlink telemetry transmission.

Power. This section provides voltage levels necessary for the proper operation of the CMC.

CMC power is furnished by two switching-regulator power supplies: a +4-volt and a +14-volt power supply which are energized by fuel cells in the electrical power system.

Input voltage from the electrical power system is chopped at a variable duty cycle and then filtered to produce the required voltages. Chopping is accomplished by varying the pulse width of a signal having a fixed repetition rate and known amplitude.

Source voltage, +28 vdc, is supplied from the electrical power system through the power switch to the control module. The control module, essentially a pulse generator, detects the difference between the primary feedback output of the power supply and a reference voltage. (A secondary feedback path is connected to the CTS for marginal-voltage test operations.) A differential amplifier detects any change in the output voltage from the desired level. The output of the differential amplifier and a 51.2-kilocycle sync pulse from the timer drive a one-shot multivibrator in the control module. The differential amplifier output determines the multivibrator pulse width. The resultant +14-volt pulse is supplied to the power switch.

The power switch filters the control module output to produce the desired d-c voltage. Additional filtering action protects the electrical power system from the wide-load variations caused by the chopping action of the power supply. The power switch also contains a temperature sensing circuit. Because of load requirements, the +4-volt power supply requires two power switches.
The power supply outputs are monitored by a failure detector consisting of four differential amplifiers. There are two amplifiers for each power supply, one for overvoltage and one for undervoltage detection. If an overvoltage condition exists, a relay closure signal indicating a power failure is supplied to the spacecraft.

2.2.3.2.2 Display and Keyboard.

The DSKYs facilitate intercommunication between the flight crew and the CMC. The DSKYs operate in parallel, with the main display console DSKY providing CMC display and control while the crew are in their couches. (See figure 2.2-2.)

Figure 2.2-2. Display and Keyboard

GUIDANCE AND NAVIGATION SYSTEM
The exchange of data between the flight crew and the CMC is usually initiated by crew action; however, it can also be initiated by internal computer programs. The exchanged information is processed by the DSKY program. This program allows the following five different modes of operation:

- **Display of Internal Data.** Both a one-shot display and a periodically updating display (called monitor) are provided.

- **Loading External Data.** As each numerical character is entered, it is displayed in the appropriate display panel location.

- **Program Calling and Control.** The DSKY is used to initiate a class of routines which are concerned with neither loading nor display. Certain routines require instructions from the operator to determine whether to stop or continue at a given point.

- **Changing Major Mode.** The initiation of large scale mission phases can be commanded by the operator.

- **Display of PGNCS Caution and Status.** The DSKY is used to display the status of the ISS, OSS, and CMC and to provide an indication of hardware and software cautions.

Displays. The displays consist of eleven status and caution indicators, three decimal displays and three decimal or octal registers. The function of the indicators and displays is as follows:

<table>
<thead>
<tr>
<th>Indicator/Display</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>UPLINK ACTY light</td>
<td>On when the CMC has received a complete 16 bit digital uplink message or during the rendezvous navigation program the gimbal angle changes are greater than 10 degrees to align the CSM to the desired tracking attitude and the astronaut has disabled the automatic tracking.</td>
</tr>
<tr>
<td>NO ATT light</td>
<td>Lighted when the ISS is in a coarse align mode.</td>
</tr>
<tr>
<td>STBY light</td>
<td>On when the CMC is in the standby mode.</td>
</tr>
<tr>
<td>Indicator/Display</td>
<td>Function</td>
</tr>
<tr>
<td>--------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>KEY REL light</td>
<td>Lighted when an internal display desires the use of the DSKY and the astronaut is using the DSKY or the astronaut presses a key (exceptions: PRO, RSET and ENTR) when an internal flashing display is currently on the DSKY or the astronaut presses a key (exceptions: PRO, RSET and ENTR) on top of his Monitor Verb display.</td>
</tr>
<tr>
<td>OPR ERR light</td>
<td>On when the operator performs an improper sequence of key depressions.</td>
</tr>
<tr>
<td>TEMP light</td>
<td>Lighted when the CMC receives a signal from the IMU temperature control that the stable member is outside of the temperature range of 126.3 to 134.3 °F.</td>
</tr>
<tr>
<td>GIMBAL LOCK light</td>
<td>On when the middle gimbal angle exceeds ±70° from its zero position.</td>
</tr>
<tr>
<td>PROG light</td>
<td>Lighted when the internal program detects computational difficulty.</td>
</tr>
<tr>
<td>RESTART light</td>
<td>On when the CMC detects a temporary hardware or software failure.</td>
</tr>
<tr>
<td>TRACKER light</td>
<td>Lighted when the CMC receives a signal from the OCDU indicating a failure or the rendezvous navigation program reads VHF range information but the Data Good discrete is missing.</td>
</tr>
<tr>
<td>COMP ACTY light</td>
<td>On when the CMC is occupied with an internal sequence.</td>
</tr>
<tr>
<td>PROG display</td>
<td>Provides a decimal display of the current mission program in sequence.</td>
</tr>
<tr>
<td>VERB display</td>
<td>Provides a decimal display of the verb (action) being performed.</td>

SYSTEMS DATA

<table>
<thead>
<tr>
<th>Indicator/Display</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>NOUN display</td>
<td>Provides a decimal display of the noun (location or register) where the action (verb) is being performed.</td>
</tr>
<tr>
<td>REGISTER 1, 2 and 3</td>
<td>Provides a display of the contents of registers or memory locations.</td>
</tr>
</tbody>
</table>

The keyboard consists of ten numerical keys (pushbuttons) labeled 0 through 9, two sign keys (+ or -) and seven instruction keys: VERB, NOUN CLR (clear), PRO (proceed), KEY REL (key release), ENTR (enter), and RSET (reset).

Whenever a key is pressed, +14 vdc is applied to a diode encoder which generates a unique five-bit code associated with that key. There is, however, no five-bit code associated with the PRO key. If a key on the main panel DSKY is pressed, the five-bit code associated with that key is entered into bit positions 1 through 5 of input channel 15 of the CMC. Note that this input will cause a request for the KEYRUPT 1 program interrupt. If a key on the navigation panel DSKY is pressed, the five-bit code associated with that key is entered into bit position 1 through 5 of input channel 16 of the CMC. Note that this input will cause a request for the KEYRUPT 2 program interrupt. The function of the keys is as follows:

<table>
<thead>
<tr>
<th>Pushbutton</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 through 9 pushbuttons</td>
<td>Enters numerical data, noun codes, and verb codes into the CMC.</td>
</tr>
<tr>
<td>+ and - pushbuttons</td>
<td>Informs the CMC that the following numerical data is decimal and indicates the sign of the data.</td>
</tr>
<tr>
<td>NOUN pushbutton</td>
<td>Conditions the CMC to interpret the next two numerical characters as a noun code and causes the noun display to be blanked.</td>
</tr>
<tr>
<td>CLR pushbutton</td>
<td>Clears data contained in the data displays. Pressing this key clears the data display currently being used. Successive depressions clear the other two data displays.</td>
</tr>

</tr>
</tbody>
</table>

**Verb-Noun Formats.** A noun may refer to a device, a group of computer registers or a group of counter registers, or it may simply serve to convey information without referring to any particular computer register. The noun is made up of 1, 2, or 3 components, each component being entered separately as requested by the verb code. As each component is keyed, it is displayed on the display panel with component 1 displayed in REGISTER 1, component 2 in REGISTER 2, and component 3 in REGISTER 3. There are two classes of nouns: normal and mixed. Normal nouns (codes 01 through 39) are those whose component members refer to computer registers which have consecutive addresses and use the same scale factor when converted to decimal. Mixed nouns (codes 40 through 99) are those whose component members refer to nonconsecutive addresses or whose component members require different scale factors when converted to decimal, or both.
A verb code indicates what action is to be taken. It also determines which component member of the noun group is to be acted upon. For example, there are five different load verbs. Verb 21 is required for loading the first component of the selected noun; verb 22 loads the second component; verb 23 loads the third component; verb 24 loads the first and second component; and verb 25 loads all three components. A similar component format is used in the display and monitor verbs. There are two general classes of verbs: regular and extended. The regular verbs (codes 01 through 39) deal mainly with loading, displaying, and monitoring data. The extended verbs (codes 40 through 99) are principally concerned with calling up internal programs whose function is system testing and operation.

Whenever data is to be loaded by the operator, the VERB and NOUN lights flash, the appropriate data display register is blanked, and the internal computer storage register is cleared in anticipation of data loading. As each numerical character is keyed in, it is displayed in the proper display register. Each data display register can handle only five numerical characters at a time (not including sign). If an attempt is made to key in more than five numerical characters at a time, the sixth and subsequent characters are simply rejected but they do appear in the display register.

The + and - keys are accepted prior to inserting the first numerical character of REGISTER 1, REGISTER 2, or REGISTER 3; if keyed in at any other time, the signs are rejected. If the 8 or 9 key is actuated at any time other than while loading a data word preceded by a + or - sign, it is rejected and the OPR ERR light goes on.

The normal use of the flash is with a load verb. However, there are two special cases when the flash is used with verbs other than load verbs.

- Machine Address to be Specified. There is a class of nouns available to allow any machine address to be used; these are called "machine address to be specified" nouns. When the "ENTR," which causes the verb-noun combination to be executed, senses a noun of this type the flash is immediately turned on. The verb code is left unchanged. The operator should load the complete machine address of interest (five-character octal). This is displayed in REGISTER 3 as it is keyed in. If an error is made in loading the address, the CLR key may be used to remove it. Pressing the ENTR key causes execution of the verb to continue.
SYSTEMS DATA

- Change Major Mode. To change major mode, the sequence is VERB 37 ENTR. This causes the noun display register to be blanked and the verb code to be flashed. The two-character octal major mode code should then be loaded. For verification purposes, it is displayed as it is loaded in the noun display register. The entry causes the flash to be turned off, a request for the new major mode to be entered, and new major mode code to be displayed in the PROG display register.

The flash is turned off by any of the following events:

- Final entry of a load sequence.
- Entry of verb "proceed without data" (33) or depression of PRO pb.
- Entry of verb "terminate" (34).

It is important to conclude every load verb by one of the aforementioned three, especially if the load was initiated by program action within the computer. If an internally initiated load is not concluded validly, the program that initiated it may never be recalled. The "proceed without data" verb is used to indicate that the operator is unable to, or does not wish to, supply the data requested, but wants the initiating program to continue as best it can with old data. The "terminate" verb is used to indicate that the operator chooses not to load the requested data and also wants to terminate the requesting routine.

Keyboard Operation

The standard procedure for the execution of keyboard operations consists of a sequence of seven key depressions:

VERB $V_2$ VERB $V_1$ NOUN $N_2$ NOUN $N_1$ ENTR

Pressing the VERB key blanks the two verb lights on the DSKY and clears the verb code register in the CMC. The next two numerical inputs are interpreted as the verb code. Each of these characters is displayed by the verb lights as it is inserted. The NOUN key operates similarly with the DSKY noun lights and CMC noun code register. Pressing the ENTR key initiates the program indicated by the verb-noun combination displayed on the DSKY. Thus, it is not necessary to follow a standard procedure in keying verb-noun codes into the DSKY. It can be done in reverse order, if desired, or a previously inserted verb or noun can be used without re-keying it. No action is taken by the CMC in initiating the verb-noun-defined program until the ENTR key is actuated. If an error is noticed in either the verb code or noun code, prior to actuation of the ENTR key, it can be corrected simply by pressing the corresponding VERB or NOUN key and inserting the proper code. The ENTR key should not be actuated until it has been verified that the correct verb and noun codes are displayed.
If the selected verb-noun combination requires data to be loaded by
the operator, the VERB and NOUN lights start flashing on and off (about
once per second) after the ENTR key is pressed. Data is loaded in five-
character words and, as it is keyed in, it is displayed character-by-
character in one of the five-position data display registers; REGISTER 1,
REGISTER 2, or REGISTER 3. Numerical data is assumed to be octal
unless the five-character data word is preceded by a plus or minus sign,
in which case it is considered to be decimal. Decimal data must be loaded
in full five-numeral character words (no zeros may be left out); octal data
may be loaded with high-order zeros left out. If a decimal is used for
any component of a multicomponent load verb, it must be used for all com-
ponents of that verb. In other words, no mixing of octal and decimal data
is permitted for different components of the same load verb. The ENTR
key must be pressed after each data word. This tells the program that
the numerical word being keyed in is complete. The on-off flashing of
the VERB-NOUN lights terminates after the last ENTR key actuator of a
loading sequence.

The CLR key is used to remove errors in loading data as it is
displayed in REGISTER 1, REGISTER 2, or REGISTER 3. It does
nothing to the PROG, NOUN or VERB lights. (The NOUN lights are
blanked by the NOUN key, the VERB lights by the VERB key.) For
single-component load verbs or "machine address to be specified" nouns,
the CLR key depression performs the clearing function on the particular
register being loaded, provided that the CLR key is depressed before the
ENTR key. Once the ENTR key is depressed, the CLR key does nothing.
The only way to correct an error after the data is entered for a single-
component load verb is to begin the load verb again. For two- or three-
component load verbs, there is a CLR backing-up feature. The first
depression of the CLR key clears whichever register is being loaded.
(The CLR key may be pressed after any character, but before its entry.)
Consecutive CLR key actuations clear the data display register above the
current one until REGISTER 1 is cleared. Any attempt to back up (clear)
beyond REGISTER 1 is simply ignored. The CLR backing up function
operates only on data pertinent to the load verb which initiated the loading
sequence. For example, if the initiating load verb were a "write second
component into" type only, no backing up action would be possible.

The numerical keys, the CLR key, and the sign keys are rejected
if depressed after completion (final entry) of a data display or data load
verb. At such time, only the VERB, NOUN, ENTR, RSET, or KEY
REL inputs are accepted. Thus, the data keys are accepted only after
the control keys have instructed the program to accept them. Similarly,
the + and - keys are accepted only before the first numerical character
of REGISTER 1, REGISTER 2, and REGISTER 3 is keyed in, and
at no other time. The 8 or 9 key is accepted only while loading a data
word which is preceded by a + or - sign.

GUIDANCE AND NAVIGATION SYSTEM

Mission Basic Date 15 April 1969 Change Date 16 July 1969 Page 2.2-26
THE DSKY CAN ALSO BE USED BY INTERNAL COMPUTED PROGRAMS FOR SUBROUTINES. HOWEVER, ANY OPERATOR KEYBOARD ACTION (EXCEPT RSET) INHIBITS DSKY USE BY INTERNAL ROUTINES. THE OPERATOR RETAINS CONTROL OF THE DSKY UNTIL HE WISHES TO RELEASE IT. THEREFORE, WHEN HE WANTS THE DATA HE WISHES TO OBSERVE WILL NOT BE REPLACED BY INTERNALLY INITIATED DATA DISPLAYS. IN GENERAL, THE OPERATOR SHOULD RELEASE THE DSKY FOR INTERNAL USE WHEN HE HAS TEMPORARILY FINISHED WITH IT; THIS IS DONE BY PRESSING THE KEY REL KEY.

2.2.3.3 Optical Subsystem.

The optical subsystem is used for taking precise optical sightings on celestial bodies and for taking fixes on landmarks. These sightings are used for aligning the IMU and for determining the position of the spacecraft. The system includes the navigational base, two of the five CDUs, parts of the power and servo assembly, controls and displays, and the optics, which include the scanning telescope (SCT) and the sextant (SXT).

2.2.3.3.1 Optics.

The optics consist of the SCT and the SXT mounted in two protruding tubular sections of the optical base assembly. The SCT and SXT shaft axes are aligned parallel to each other and afford a common line-of-sight (LOS) to selected targets. The trunnion axes may be parallel or the SCT axis may be offset, depending upon the mode of operation.

The sextant is a highly accurate optical instrument capable of measuring the included angle between two targets. Angular sightings of two targets are made through a fixed beam splitter and a movable mirror located in the sextant head. The sextant lens provides 1.8-degree true field-of-view at 28X magnification. The movable mirror is capable of sighting a target to 50 degrees LOS from the shaft axis. The mechanical accuracy of the trunnion axis is twice that of the LOS requirement because of mirror reflection which doubles any angular displacement in trunnion axis.

The scanning telescope is similar to a theodolite in its ability to accurately measure elevation and azimuth angles of a single target using an established reference. The lenses provide 60-degree true field-of-view at 1X magnification. The telescope allowable LOS errors are one minute of arc-rams in elevation with maximum repeatability of 15 arc-seconds and approximately 40 arc-seconds in shaft axis.

2.2.3.2 Coupling Data Unit.

The identical coupling data unit (CDU) used in the ISS is also used as part of the OSS. Two channels of the CDU are used, one for the SXT
shaft axis and one for the SXT trunnion axis. These CDU channels repeat the SXT shaft and trunnion angles and transmit angular change information to the CMC in digital form. The angular data transmission in the trunnion channel is mechanized to generate one pulse to the CMC for 5 arc-seconds of movement of the SXT trunnion which is equivalent to 10 arc-seconds of SLOS movement. The shaft CDU channel issues one pulse for each 40 arc-seconds of shaft movement. The location of the SXT shaft and trunnion axes are transmitted to the CDUs through 16X and 64X resolvers, located on the SXT shaft and trunnion axes, respectively. This angular information is transmitted to the CDUs in the form of electrical signals proportional to the sine and cosine of 16X shaft angle and 64X trunnion angle. During the computer mode of operation, the CDU provides digital-to-analog conversion of the CMC output to generate an a-c input to the SXT shaft and trunnion servos. This analog input to the SXT axes will drive the SLOS to some desired position. In addition, the OSS channels of the CDU perform a second function on a time-sharing basis. During a thrust vector control function, these channels provide digital-to-analog conversion between the CMC and the service propulsion system (SPS) gimbals.

2.2.4 OPERATIONAL MODES.

The PGNCS has two systems, six inertial subsystem (ISS), and three optical subsystem (OSS) modes. The system modes are listed as follows:

- Saturn takeover
- Thrust vector control.

The ISS modes are listed as follows:

- IMU turn-on
- IMU cage
- Coarse align
- Fine align
- Attitude error
- Inertial reference.

The OSS modes are listed as follows:

- Zero optics
- Manual control
- Computer control.

The moding of the system and ISS is controlled by the CDU with the exception of one mode, a cage switch on the main display and control panel. All other modes must be commanded by the CMC through the issuance of discrete moding commands to the CDU.
The modes of operation for the OSS are selected by the astronaut using controls located on the indicator control panel.

2.2.4.1 S-IVB Takeover.

The S-IVB takeover capability provides steering signals to the Saturn instrument unit autopilot. There are two modes of operation, automatic and manual. The automatic mode provides the backup capability of issuing steering commands to the IU during the boost phase. This mode is initiated by positioning the LAUNCH VEHICLE GUIDANCE switch on the main display and control panel to CMC and during the boost monitor program only. This switch arms the S-IVB takeover relay with 28 vdc and issues a discrete to the CMC. The CMC, on recognition of this input discrete, switches to a control routine which generates an S-IVB takeover discrete. The S-IVB takeover discrete allows the relay in the mode module to energize, closing the interface between the DAC and the S-IVB instrument unit.

Normally the boost monitor program monitors the CDUs, computes the difference between the desired attitude (determined by a stored polynomial) and the actual attitude, and displays the error on the FDAI. During the takeover mode the commands are computed by taking the error (difference between polynomial and actual attitude) at takeover and storing as a bias. This value is subtracted from the actual error computed on succeeding cycles and is used to issue steering commands that attempt to maintain a constant error equal to that existing at takeover.

The manual mode provides the capability of issuing rotation control commands, through the CMC, to the instrument unit. The manual mode is initiated by placing the LAUNCH VEHICLE GUIDANCE switch to the CMC position and enabling the RCS digital autopilot with an extended verb. The switch arms the S-IVB takeover relay with 28 vdc and issues a discrete to the computer. The CMC, on recognition of this discrete and the RCS digital autopilot enabled, generates the S-IVB takeover discrete.

If either rotation control is placed to a pitch, yaw, or roll breakout position, the CMC issues an error-counter-enable discrete to the CDU. The error-counter-enable discrete is buffered in the moding module, modified by the digital mode module finally allowing the error counters to be enabled. The CMC then generates a $\pm \theta_c$ pulse train to the appropriate error counter where it is accumulated and converted to a $\pm d$-c output signal by the DAC. The $\pm d$-c signal is applied to the S-IVB IU as a $0.5^\circ$/sec $\pm$ pitch or $\pm$ yaw rate command.
When the rotation control is returned to the null position, the CMC inhibits the error-counter-enable discrete to the CDU which causes the error counter to reset. This results in a 0-vdc output signal from the DAC which is applied to the S-IVB IU as a 0°/sec roll, pitch, or yaw rate command.

2.2.4.2 Thrust Vector Control.

This system mode is initiated by CMC program control.

The CMC commands a TVC discrete which energizes the TVC relay closing the interface between the CDU DAC and the SPS gimbal servo amplifiers.

The computer also issues an OSS error-counter enable and an ISS error-counter enable. The computer, when all operating requirements are met, issues an SPS engine-on command.

The ISS read counters are repeating the gimbal angle changes indicating to the CMC the present spacecraft attitude. The accelerometers provide the program with ΔV inputs. These data are used to compute an attitude error and a SPS steering signal.

The attitude error is converted to a pulse train which is used to increment the CDU ISS error counters. The contents of these counters are converted to analog and displayed as they were in the attitude error display mode. The read counter input to the error counter is inhibited, allowing the error counter to be incremented or decremented only by CMC commands.

The OSS error counters are incremented by a Δθ command proportional to the steering signals required to steer the spacecraft on the proper trajectory. The error counter can operate completely independent of the read counter circuitry so the condition of the OSS is immaterial to this operation. The error counter contents are converted to analog 800 cps and then to a ±d-c voltage in the CDU OSS DAC. The pitch or yaw steering signal is routed through the TVC relay in the mode module to the SPS gimbal servo amplifiers. The TVC mode is complete when the spacecraft reaches the required velocity and the engine-off discrete is issued by the CMC. Each Δθ pulse from the CMC changes the SPS gimbals by 85 arc-seconds.

2.2.4.3 IMU Turn-On Mode.

The purpose of the IMU turn-on mode is to initialize the ISS by driving the IMU gimbals to zero, and clearing and inhibiting the CDU read counters and error counters. The IMU turn-on mode is initiated.
by applying IMU operate power to the subsystem. The computer issues
two CDU discrete's required for this mode, CDU zero and coarse align.
The computer also issues the turn-on delay complete discrete to the ISS
after 90 seconds.

When IMU operate power is applied to the subsystem, the computer
receives an ISS power-on discrete and a turn-on delay request. The
computer responds to the turn-on delay request by issuing the CDU zero
and coarse align discrete's to the CDU. To prevent PIPA torquing for
90 seconds during the IMU turn-on mode, an inhibit is applied to the
pulse torque power supply. This same inhibit is present when a com-
puter warning has been issued. The CDU zero discrete clears and
inhibits the read counters and error counters. The ISS operate power
(+28 vdc) is routed through the de-energized contacts of the auto cage
control relay to energize the cage relay. A 0-vdc signal, through the
energized contacts of the cage relay, energizes the coarse-align relay.
The energized contacts of the coarse-align relay switch the gimbal servo
amplifier demodulator reference from 3200 cps to 800 cps, and close the
IMU cage loop through the energized contacts of the cage relay. The
course-align relay is held energized by the CDU coarse-align discrete's
and the energized contacts of the cage relay. The IMU gimbals will
drive to the zero reference position using the sine output of the IX gimbal
resolvers (sin 6).

After 90 seconds, the computer issues the ISS turn-on delay com-
dete discrete which energizes the ISS turn-on control relay. The auto
cage control relay is energized by the ISS turn-on control relay. The
ISS turn-on control relay then locks up through the energized contacts of
the auto cage control relay. Energizing the auto cage control relay also
removes the turn-on delay request and de-energizes the cage relay. This
removes the sin 6 signal and applies the coarse-align output to the gimbal
servo amplifier. Energizing the ISS turn-on control relay removes the
pulse torque power supply inhibit. The 90-second delay enables the gyro
wheels time to reach their operating speed prior to closing the stabiliza-
tion loops. The pulse torque power supply inhibit prevents accelerometer
torquing during the 90 seconds.

2.2.4.4 IMU Cage Mode

The IMU cage mode is an emergency mode which (1) allows the
astronaut to recover a tumbling IMU by setting the gimbals to zero, and
(2) to establish an inertial reference. The IMU cage mode can also be
used to establish an inertial reference when the CSS is not activated.

The IMU cage mode is manually initiated by closing the spring-
loaded cage switch on the main display and control panel for sufficient
time to allow the IMU gimbals to settle at the zero position (5 seconds
maximum). The IMU gimbal zeroing can be observed on the FDAI.
If the mode is commanded to recover a tumbling IMU after the IMU turn-on mode is completed, closing the IMU cage switch will cause the IMU gimbals to drive to zero. When the switch is released, the ISS will enter the inertial reference mode.

If the IMU cage mode is commanded to establish an inertial reference with the CSS in standby or off, the closing of the IMU cage switch will cause the IMU gimbals to drive to zero. When the switch is released, the inertial reference mode will be established.

Closing the IMU cage switch energizes the cage and coarse-align relays, which apply the sin $\theta$ signals to the gimbal servo amplifier, and sends an IMU cage discrete to the computer. Releasing the switch causes the cage and coarse-align relays to de-energize. When the coarse-align relay is de-energized, the stabilization loops are closed. The computer, upon receiving the IMU cage signal, discontinues sending all of the following discrete and control signals:

- Error-counter enable (OSS)
- Error-counter enable (ISS)
- Coarse-align enable
- TVC enable
- SPS engine on (CSM only)
- Gyro-command enable (torquing)
- $\pm X$ and/or $\pm Y$ optics CDU - D/A
- $\pm X$ (outer), $\pm Y$ (inner), $\pm Z$ (middle) IMU CDU - D/A
- $\pm X$, $\pm Y$, $\pm Z$ gyro select
- Gyro set pulses.

The IMU cage mode should not be used indiscriminately. It is intended only as an emergency recovery function for a tumbling IMU. During the IMU cage mode, IMU gimbal rates are sufficient to cause the gyro to be driven into their rotational and radial stops because of no CDU rate limiting. This action causes both temporary and permanent (if gyro torquing was in process during cage) bias shifts on the order of several MERU.

2.2.4.5 IMU Coarse Align.

The coarse-align mode of operation is mechanized to allow the computer to rapidly align the IMU to a desired position with a limited degree of accuracy. The computer issues two discrete to the CDU in this mode, coarse-align and error-counter enable.

The coarse-align discrete is routed through the moding module where it is buffered. One buffered output provides a ground path to the coarse-align relay energizing the relay. The energized relay opens the
gyro preamp output, replaces the normal 3200-cps demodulator reference with an 800-cps reference, and routes the 800-cps coarse-align output from the DAC into the gimbal servo amplifier demodulator, thereby allowing any 800-cps signal generated within the DAC to drive the gimbal until the DAC output is zero vrms.

The buffered coarse-align discrete and error-counter-enable discrete are routed from the moding module to the digital mode module for logical manipulations. The discretes at 0-vdc level are accepted by the error counter and logic module as moding commands enabling the error counter, and allowing the transfer of $\Delta \theta$ angles from the read counter to the error counter.

After the logic circuitry has been set up to accept commands from the computer, the CMC will begin transmitting $\pm \Delta \theta_c$ pulse trains at 3200 pps. These pulses, each equivalent to a change in gimbal angle of 160 arc-seconds, are accumulated in the error counter. The nine stages of the error counter are used solely to control ladder switches in the digital-to-analog converter module.

The $\Delta \theta_c$ pulse train is routed through a buffer stage in the DAC. The first $\Delta \theta_c$ pulse arriving at the EC&L logic will determine the direction the counter is to count, and will also provide a DAC-polarity control to the DAC. The polarity control provides an in-phase or an out-of-phase reference to the resistive-ladder network through switches selected by the nine-bit error counter. An 800-cps analog signal will be generated at the ladder, the amplitude of which is dependent on the error counter content and the phase on the polarity of the input command $\Delta \theta_c$.

The ladder output is mixed with the coarse- and fine-resolver errors, after nulling, from the coarse module and the main summing amplifier module, respectively. These errors are out of phase with the ladder output and will act as a degenerative feedback providing rate limiting to the coarse-align loop drive rates.

The 800-cps mixing amplifier output of the DAC is routed through the coarse-align relay into the gimbal servo amplifier, causing the gimbal to drive in the direction commanded by the CMC.

The changing gimbal angles are recognized by the error-detection circuits in the coarse module and the main summing amplifier. These detected errors, recognized by the error counter logic circuitry, allow the $\Phi_4$ pulse train at 6400 pps to increment the read counter. The incrementing read counter will close attenuation switches in the coarse, quadrant select, the main summing amplifier modules nulling the sine and cosine voltage inputs from 1X and 16X resolver into the error-detect circuits.
As the read counter is being incremented, the output of the first stage is routed through logic in the EC&L module, through a buffer in the DAC, and out to the CMC as an increase in gimbal angle of 40 arc-seconds. The output of the third stage of the counter, at 160 arc-seconds per pulse, is recognized in the EC&L logic as an incremental value to be entered into the error counter in the opposite direction to the commanded $\Delta \theta$. If $\Delta \theta$ is positive, the error counter is counted up and the $\Delta \theta_s$ from the read counter decrements the counter. For each read counter pulse into the error counter, the total content will decrease the DAC output and the rate of drive. When the number of digital feedback pulses equal the commanded pulse number, the error counter will be empty and the DAC output should be zero.

The limited read counter incrementing rate, and the fact that the fine error input to the DAC increases in proportion to $\theta - \varphi$ as the drive rate exceeds the range controlled by the fine system, limits the gimbals rate of drive to a maximum of 35 degrees per second.

2.2.4.6 IMU Fine Align.

The fine-align mode of operation allows the computer to accurately align the IMU to a predetermined gimbal angle within seconds of arc. The computer does not command any CDU discretes during this mode of operation; therefore, the read counter circuitry will repeat the changing gimbal angles exactly as was done in the coarse-align mode. The computer will keep track of the gimbal angle to within 40 arc-seconds.

The commanding signals for the fine-align mode are generated in the time-shared, fine-align electronics. The computer first issues a torque-enable discrete which applies 28 vdc and 120 vdc to the binary current switch and the differential amplifier precision voltage reference circuit, allowing the circuit to become operative. The circuit switch is reset to allow a dummy current, which is equal to the torquing current, to flow. This allows the current to settle to a constant value prior to its being used for gyro torquing. A gyro is then selected for either plus or minus torquing. After the preceding discretes have been issued, the computer then sends set commands or fine-align commands to the set side of the current switch. The pulse turns on the selected plus or minus torque current to the gyro, causing the float to move. The resulting signal generator output causes the platform to be driven through an angle equal to the commanded angle. The CMC will receive inputs from the CDU read counter indicating the change in gimbal angle.

The number of torquing pulses sent from the CMC to the torquing electronics is computed, based on the angle of the gimbal at an instant of time and a desired alignment angle. The difference is converted into the number of pulses necessary to drive the gimbal through the difference.
angle. Each pulse sent is equivalent to 0.615 arc-second of gimbal displacement. The required number of fine-align pulses is computed only once and is not recomputed based on the gimbal angle after the desired number of pulses have been sent. The fine-align loop operation is open-loop as far as the computer is concerned.

The fine-align pulses generated by the CMC are issued in bursts at a bit rate of 3200 pulses per second. The fine-align electronics will allow the torquing current to be on in the direction chosen by computer logic for the duration of the pulse burst.

2.2.4.7 Attitude Error Display Mode.

The attitude error display mode of the inertial subsystem allows the computer to display to the operator, in analog fashion, an attitude error. In this mode of operation, only the CDU error-counter-enable discrete is generated by the computer. In this mode of operation, the computer is again informed of the gimbal angle and any changes to it through the read counter and the analog-to-digital conversion associated with it. The read counter 2-degree output is routed through logic in the EC&L module through the DAC buffer to the CMC.

The computer is then aware of the present attitude of the spacecraft. The digital autopilot program has a computed desired attitude associated with the present time and position of the spacecraft. Any difference between the desired and actual is an attitude error. The attitude error is converted to $\Delta \theta_c$ pulses, each pulse being equivalent to 160 arc-seconds of error, which are sent to the error counter at a rate of 3200 pps. The error counter is incremented to contain the number of pulses commanded. The contents of the error counter are converted to an 800-cps error signal by the DAC. The phase of the DAC output is determined by logic in the EC&L module, based on whether the input command was a plus or minus $\Delta \theta$. The 800 cps with a maximum amplitude of 5 v rms zero or biphase is displayed on the attitude error needles of the FDAI as an attitude error. The digital feedback from the read counter to the error counter is disabled during this mode of operation allowing only the CMC-generated $\Delta \theta$ commands to increment or decrement the error counter.

The spacecraft attitude can also be displayed on the FDAI. This information is taken from the 1X gimbal angle resolver sine and cosine windings. Pitch, yaw, and roll can be displayed from the inner, middle, and outer gimbals, respectively.

2.2.4.8 Inertial Reference Mode.

The inertial reference mode of operation is a mode of operation in which no computer discretes are being issued by the computer to any part
of the ISS. This mode is used as a means of obtaining an inertial reference only. This reference is taken from the 1X gimbal angle resolver sine and cosine windings. The reference can be displayed on the FDAI or used as an input to the attitude set relays of the SCS.

In this mode of operation, the 25 IRIGs hold the stable platform inertially referenced. The CDU read counter will continuously monitor the changing gimbal angles because of spacecraft motion and indicate to the CMG the changing angles. The error counter and the DAC are not used in this mode of operation.

2.2.4.9 Zero Optics Mode.

During the zero optics mode, the shaft and trunnion axes of the SXT are driven to their zero positions by taking the outputs of the transmitting resolvers (1X and 64X in trunnion and 1/2X and 16X in shaft) and feeding them through the two-speed (2X) switches to the motor drive amplifier (MDA). The MDA in turn drives loops to null positions as indicated by zero output from the resolvers. The SCT shaft and trunnion axes follow to a zero position. After 15 seconds, the computer will issue a CDU zero discrete, and will initialize the shaft and trunnion counters in preparation for receiving new data from the CDU.

The zero optics mode is selected by the flight crew. Placing the ZERO switch to ZERO position will energize a relay in the PSA via a relay driver, which, in turn, will energize the two-speed switch. The computer is notified of the zero optics mode by a signal from the zero switch when the change from off to zero position occurs.

2.2.4.10 Manual Mode Operation.

The manual mode can be selected to operate under either direct hand control or resolved hand control. Independent control of the SCT trunnion is possible in both of these mode variations.

2.2.4.10.1 Manual Direct Operation.

When in this mode, the hand controller outputs are applied directly to the SXT shaft and trunnion motor drive amplifiers. Forward and back motion of the hand controller commands increasing and decreasing trunnion angles, and right and left motion of the hand controller commands increasing and decreasing shaft angles, respectively. The target image motion is in the R-M coordinate system, the position of which is dependent upon the position of the SXT shaft.

The apparent speed of the image motion can be regulated by the flight crew by selecting either low, medium, or high controller speed on
the indicator control panel. This regulates the voltage applied to the motor drive amplifier, \( A_s \) and \( A_t \); therefore, the shaft and trunnion drive rates. The maximum rates are approximately 20 degrees per second for the shaft and 10 degrees per second for the trunnion.

2.2.4.10.2 Slave Telescope Modes.

The slave telescope modes provide for alternate operation of the telescope trunnion while the SXT is being operated manually. The alternate modes are selected by the TELTRUN switch on the mode control panel. There are three possible selections, SLAVE to SXT, 0°, and 25°. With this switch in the SLAVE to SXT position, the SCT trunnion axis is slaved to the SXT trunnion; this is the normal operating position for the SCT. With the switch in the 0° position, the SCT trunnion is locked in a zero position by the application of a fixed voltage to the SCT trunnion 1X receiving resolver. This will cause this position loop to null in a zero orientation. Therefore, the centerline of the SCT 60-degree field-of-view is held parallel to the LLOS of the SXT.

With the switch in the 25° position, an external voltage is applied to the same 1X receiving resolver which will cause the SCT trunnion position loop to null out so that the centerline of the 60-degree field-of-view is offset 25 degrees (\( A_t \) of SCT at 12.5 degrees) from the LLOS of the SXT. This position of the SCT trunnion will allow the landmark to remain in the 60-degree field-of-view while still providing a total possible field-of-view of 110 degrees if the SCT shaft is swept through 360 degrees.

2.2.4.10.3 Manual Resolved Operation.

When in this mode, the hand controller outputs are put through a matrix transformation prior to being directed to the shaft and trunnion motor drive amplifiers. The matrix transformation makes the image motion correspond directly to the hand controller motion. This is up, down, right, and left motions of the hand controller command; the target image moves up, down, right, and left respectively, in the field of view. In other words, the image motion is in the X-Y spacecraft coordinate system. The matrix transformation takes place in two steps. The outputs of the hand controller are routed to the 1X resolver on the SXT shaft. Here the drive signals, \( A_s \) and \( A_t \), are transformed by the sine and cosine functions of the shaft angle (\( A_t \)). One of the two outputs of the 1X resolver is sent to the SXT trunnion motor drive amplifier. The second output is then resolved through the SLOS angle (\( A_{LOS} \)) so that the target image motion will be independent of SLOS angle. This is accomplished by the cosecant computing amplifier (CSC) and the 2X computing resolver located on the SXT trunnion axis. The net result is that the shaft drive rate, \( A_s \), is inversely proportional to the sine of the SLOS angle. The speed controller is also operational in this mode.
The MARK and MARK REJECT buttons on the indicator control panel are utilized to instruct the computer that a navigational fix has taken place, and that SXT shaft and trunnion position and the time should either be recorded or rejected. The mark command is generated manually by the flight crew which energizes the mark relay. The mark relay transmits a mark command to the computer. If an erroneous mark is made, the mark reject button is depressed; this will generate a "mark reject" command to the computer.

**Computer Mode Operation.**

The computer-controlled operation is selected by placing themoding switch in computer position. The mechanization of this loop is chosen by the computer program that has been selected by the flight crew. The operation of the SXT under computer control is accomplished by completing the circuit from the CDU digital-to-analog converters (DAC) to the shaft and trunnion motor drive amplifier. The computer can then provide inputs to these amplifiers via a digital input to the CDU, which are converted in the DAC to an 800-cycle signal that can be used by the MDA. This mode is used when it is desired to look at a specific star for which the computer has the corresponding star coordinates. The computer will also know the attitude of the spacecraft from the position of the IMU gimbals and will, therefore, be able to calculate the position of the SXT axes required to acquire the star. The computer can then drive the shaft and trunnion of the SXT to the desired position via the DAC.

**POWER DISTRIBUTION.**

The guidance and navigation circuit breakers (panel 5) supply a-c and d-c power to switches on panels 5 and 100 and directly to the PSA and CMC. The panel 5 switch (G/N PWR) supplies AC1 or AC2 power to the PSA (figure 2.2-4) where it is routed to the dimmer power supply. The output of the dimmer power supply is provided to the following:

- Caution and warning lamp on LEB panel 122
- Star acquired lamp on LEB panel 122
- TPAC readout on LEB panel 122
- Optics (SCT and SXT) reticles

The panel 100 switches (G/N POWER - IMU and OPTICS) supply the d-c power to the PSA for power to the ISS, OPTICS and CDU power supplies. The IMU HTR and COMPUTER circuit breakers supply power to the ISS temperature control circuits and the CMC power supplies.
Figure 2.2-3. PGNCS Functional Diagram (Sheet 1 of 2)
Figure 2.2-4. PGNCS Power Distribution
Circuit breakers on panel 226 supply a-c power to dimmer controls on panels 8 and 100 for lighting on the DSKYs and LEB panel 122. The circuit breakers (LMDC-AC1 and LEB AC2) supply the a-c power to variable transformers in panels 8 and 100 and to isolation transformers (figure 2.2-5) for control of intensity of the status and key integral lamps on the DSKYs and integral lamps on LEB panel 122. The intensity of the displays on the DSKYs are controlled by rheostats on panels 8 and 100.
